

TITLE

Optical sensor

CROSS-REFERENCE TO RELATED APPLICATIONS

This application claims priority to application serial  
5 no. PCT/IB2004/000796, filed on January 24, 2004.

BACKGROUND OF THE INVENTION

The present invention relates to an optical sensor for the monitoring of combustion processes in a combustion chamber and to a method for the manufacture of said sensor.

10 In internal combustion engines, for example spark ignition engines or diesel engines, optical sensors are used to monitor combustion. Recording the brightness over time in a combustion chamber on the one hand provides valuable data useful as boundary conditions for computational models since the temperature can be inferred from the brightness. On the 15 other hand, the soot concentration within the combustion chamber can be deduced by determining the brightness. Due to increasingly harsh regulations with respect to gas emissions legislation a lot of effort is undertaken to decrease the soot 20 formation during combustion in engines. Optical sensors provide valuable data for these developments.

25 Thus, as described in EP 0593413 for example a plurality of optical sensors are arranged in the cylinder head gasket of an internal combustion engine. For this purpose, the diameter of such sensors must not be larger than about 2 mm. The angular coverage of sensors in this application is 10 to 40°.

30 A plurality of sensors in the combustion chamber is provided for this field of application to be able to cover the spatial extension of combustion. In this case a correspondingly smaller angular coverage is provided.

Other fields of application provide a single sensor which is intended to collect as much as possible of the light emitted in the combustion chamber. A large angular coverage is required from such a sensor. Sensors used for this purpose

35 have an angular coverage of about  $110^\circ$ . The diameter of such sensors is more than 10 mm. Therefore, such sensors cannot be built into a spark plug or heater plug.

These sensors are for example mounted directly into the cylinder head in openings provided for this purpose.

10 Difficulties arise during mounting and sealing the resulting openings.

15 Another possibility is to mount an optical sensor into a spark plug of a spark ignition engine or into a heater plug of a diesel engine. This is for example achieved by means of a thread provided on the sensor. This provides the advantage of rapid assembly and disassembly and does not require additional mechanical work on the engine.

50 In general, optical sensors are made of a lens which lets pass the light impinging onto one surface and emits it from the opposite surface. Subsequently, the light impinges on a waveguide which conducts the light to a monitoring device. At this monitoring device, the light signal is processed into data and edited in a form which enables further evaluation of the information.

55 The lens as well as one end of the waveguide are usually surrounded and kept together by a sheath. The difficulties in centering are mainly encountered in the case of very small diameters and depths of the lenses.

#### BRIEF SUMMARY OF THE DISCLOSURE

50 It is therefore an object of the present invention to suggest an optical sensor having an angular coverage of at least  $130^\circ$  and having a cross section of not more than 10 mm, preferably less than 6.5 mm, in particular 2.5 to 3.5 mm.

55 In general, optical sensors are made of a lens which lets pass the light impinging onto one surface and emits it from the opposite surface. Subsequently, the light impinges on a waveguide which conducts the light to a monitoring device. At this monitoring device, the light signal is processed into

70 data and edited in a form which enables further evaluation of the information.

75 The lens as well as one end of the waveguide are usually surrounded and kept together by a sheath. The difficulties in centering are mainly encountered in the case of very small diameters and depths of the lenses.

80 It is therefore an object of the present invention to suggest a method by which the lens of an optical sensor can be centered with the highest precision.

85 This object has been achieved by the preambles of the independent claims.

90 The present disclosure relates to an optical sensor for the monitoring of combustion processes in a combustion chamber wherein the optical sensor at least comprises a lens system facing the combustion chamber, a waveguide and a sheath surrounding the lens system and one end of the waveguide characterized in that the lens system consists of at least one essentially plano-concave lens and a double concave lens wherein the planar surface of the plano-concave lens is exposed to the combustion chamber. The disclosure also relates to a method for the manufacture of said sensor.

#### BRIEF DESCRIPTION OF THE DRAWING

95 The present invention will be explained with respect to the following drawing. The Figure shows:

100 Fig. 1 an embodiment according to the invention of an optical sensor

#### DETAILED DESCRIPTION OF EMBODIMENTS

105 Fig. 1 shows the tip of an optical sensor. In this embodiment a lens system consisting of two lenses 1, 2 is shown. On of the lenses 1 is a plano-concave lens wherein the planar surface faces the combustion chamber. The second lens 2 is a double concave lens and arranged directly behind the first lens 1. Both lenses are arranged within a sheath 4. A waveguide 5 also extends into the sheath 4 with one end. The

waveguide 5 also is positioned with high precision. By the  
05 waveguide 5 the collected light is guided and finally arrives  
at a suitable monitoring device which processes the light to  
generate a signal and evaluates it for other purposes. A  
sensor of this type can be assembled in a spark plug or a  
heater plug, for example by means of a thread provided on the  
sensor.

10 The lens system 1, 2 provides a beam path having an  
angular coverage of 110° to 140°. Lens systems of 130 to 135°  
have been found to serve this purpose very well.

15 The lenses 1, 2 used are made of a material having a  
coefficient of thermal expansion at 0 to 400°C of less than  
10.5·10<sup>-6</sup> K<sup>-1</sup>, particularly between 0.15·10<sup>-6</sup> K<sup>-1</sup> and 6.7·10<sup>-6</sup> K<sup>-1</sup>. The surface area of least lens 1 must be solderable or  
solderably equipped, for example with a metal plating. Both  
lenses 1, 2 are intended to transmit light waves up to 10 µm,  
20 at least in a range of 0.2 to 2 µm. For example, sapphire and  
quartz glass have been found suitable. The waveguide 5 ends  
directly in a predetermined distance of the lens 2 and is  
embraced in the area of the sheath 4. In the rear portion of  
the sensor the waveguide 5 is sealed into the sensor by  
pouring an appropriate mass 6.

25 Interesting with respect to this lens system 1, 2 is the  
possibility to produce small lenses 1, 2 and thus small  
sensors. Such sensors are intended for the assembly in a spark  
plug or heater plug. Therefore, it is desirable to fabricate  
lens systems 1, 2 having a diameter of < 8 mm, preferably < 5  
30 mm, particularly < 2.4 mm. In this way the outer diameter of  
the sheath 4 becomes < 10 mm, preferably < 6.5 mm,  
particularly 2.5 to 3.5 mm.

35 The length of the lens system 1, 2 which has to be passed  
by the light is generally at most equal to the diameter of the  
lens system 1, 2, preferably 50 to 75% of the diameter of the  
lens system 1, 2.

The lenses 1, 2 must be assembled and fixed in a centered manner and with high precision in the recess of the sheath 4. The waveguide must be assembled in a precisely predetermined 10 distance from the lens. The precision is the more required the smaller is the diameter of the lenses 1, 2. Already a small deviation from the central position deteriorates the signal or even makes it unusable. The method of the invention explained herein enables this required precise centering.

15 With respect to the recess of the sheath 4 into which they have been introduced, the lenses 1, 2 have a slackness of 5 to 10  $\mu\text{m}$ . The sheath is made of a material having a coefficient of thermal expansion in the range of 0 to  $400^\circ\text{C}$  of less than  $10.5 \cdot 10^{-6} \text{ K}^{-1}$ , particularly less than  $7 \cdot 10^{-6} \text{ K}^{-1}$ . In 50 addition, the material of the sheath 4 must be solderable and able to withstand continuous temperatures up to  $600^\circ\text{C}$  and momentary temperatures up to  $950^\circ\text{C}$ . The sheath 4 must have a spalling resistance of about 50 K/10 ms. The thermal 55 conductivity of the material of the sheath 4 should be at least 20 W/mK, preferably at least 50 W/mK. The material of the sheath 4 must be mechanically processable with a precision of  $\pm 10 \mu\text{m}$ , preferably  $\pm 5 \mu\text{m}$ .

The method for centering the lenses 1, 2 in the recess of the sheath 4 is to fill the gap 3 between the first lens 1 and the sheath 4, and optionally also the gap between the lens 2 and the sheath 4 generated by the slackness 3 with a soldering 50 paste. The soldering paste should have an upper melting point of 770 to  $1100^\circ\text{C}$  and good wettability.

55 The axial orientation of the waveguide 5 and the lens system 1, 2 must also be very precise with a small deviation of less than 10  $\mu\text{m}$ , preferably less than 5  $\mu\text{m}$ . This is achieved by deep-drawing the sheath.

#### **Summary**

— The present invention relates to an optical sensor for the monitoring of combustion processes in a combustion chamber wherein the optical sensor at least comprises a lens system facing the combustion chamber, a waveguide and a sheath surrounding the lens system and one end of the waveguide characterized in that the lens system consists of at least one essentially plane-concave lens and a double-concave lens wherein the planar surface of the plane-concave lens is exposed to the combustion chamber. The invention also relates to a method for the manufacture of said sensor.
